JC13 Rec'd PCT/PTO 22 MAR 2002

FORM PTO-1390 (REV. 5-93)		U.S. DEPARTMENT OF COMMERCE PATENT AND TRADEMARK OFFICE	CASE NO. 56/372
TRANSMITTAL LETTER TO THE UNITED STATES DESIGNATED/ELECTED OFFICE (DO/EO/US) CONCERNING A FILING UNDER 35 U.S.C. 371		U.S. APPLICATION NO. (If known, see 37 C.F.R. 1.5) 10/089321	
INTERNATIONAL APPLICATION NO. PCT/EP00/09232	INTERNATIONAL FILING DATE September 21, 2000	PRIORITY DATE CLAIMED September 24, 1999	
TITLE OF INVENTION METHOD FOR DETERMINING TIME CONSTANTS OF A REFERENCE MODEL IN A CASCADE CONTROLLING CIRCUIT			
APPLICANT(S) FOR DO/EO/US Norbert Kerner			
Applicant herewith submits to the United States Designated/Elected Office (DO/EO/US) the following items and other information:			
1. <input checked="" type="checkbox"/> This is a FIRST submission of items concerning a filing under 35 U.S.C. 371 2. <input type="checkbox"/> This is a SECOND or SUBSEQUENT submission of items concerning a filing under 35 U.S.C. 371 3. <input checked="" type="checkbox"/> This express request to begin national examination procedures (35 U.S.C. 371(f)) at any time rather than delay examination until the expiration of the applicable time limit set in 35 U.S.C. 371(b) and PCT Articles 22 and 39(1). 4. <input checked="" type="checkbox"/> A proper Demand for International Preliminary Examination was made by the 19th month from the earliest claimed priority date. 5. <input checked="" type="checkbox"/> A copy of the International Application as filed (35 U.S.C. 371(c)(2)). a. <input checked="" type="checkbox"/> is transmitted herewith (required only if not transmitted by the International Bureau). b. <input type="checkbox"/> has been transmitted by the International Bureau. c. <input type="checkbox"/> is not required, as the application was filed in the United States Receiving Office (RO/US). 6. <input checked="" type="checkbox"/> A translation of the International Application into English (35 U.S.C. 371(c)(2)). 7. <input type="checkbox"/> Amendments to the claims of the International Application under PCT Article 19 (35 U.S.C. 371(c)(3)). a. <input type="checkbox"/> are transmitted herewith (required only if not transmitted by the International Bureau). b. <input type="checkbox"/> have been transmitted by the International Bureau. c. <input type="checkbox"/> have not been made; however, the time limit for making such amendments has NOT expired. d. <input type="checkbox"/> have not been made and will not be made. 8. <input type="checkbox"/> A translation of the amendments to the claims under PCT Article 19 (35 U.S.C. 371(c)(3)). 9. <input type="checkbox"/> An oath or declaration of the inventor(s) (35 U.S.C. 371(c)(4)). 10. <input type="checkbox"/> A translation of the annexes to the International Preliminary Examination Report under PCT Article 36 (35 U.S.C. 371(c)(5)) and/or amendments under Article 34.			
Items 11. to 16. Below concern other document(s) or information included:			
11. <input type="checkbox"/> An Information Disclosure Statement under 37 CFR 1.97 and 1.98. 12. <input type="checkbox"/> An assignment document for recording. A separate cover sheet in compliance with 37 CFR 3.28 and 3.31 is included. 13. <input checked="" type="checkbox"/> A FIRST preliminary amendment. <input type="checkbox"/> A SECOND or SUBSEQUENT preliminary amendment. 14. <input type="checkbox"/> A substitute specification. 15. <input type="checkbox"/> A change of power of attorney and/or address letter. 16. <input checked="" type="checkbox"/> Other items or information: Proposed Amendment To Drawings including twelve (12) sheets of corrected drawings.

PROPOSED AMENDMENT TO DRAWINGS

35 Commissioner for Patents
Washington, D.C. 20231
Attn. Draftsman

Dear Sir:

107089321

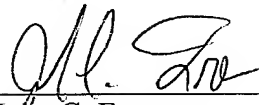

JC13 Rec'd PCT/PTO 22 MAR 2002

Applicant is submitting proposed corrections for original FIGS. 2a-b, 3-10 and 13-21. Newly proposed FIGS. 2a-b, 3-10 and 13-21 provide English-language translations for the legends and/or numerals for the drawings.

5 The additions have been indicated in red ink. Furthermore, it is not believed that the corrections involve new matter. Accordingly, please indicate whether the corrections are acceptable in the next Office Action.

Respectfully submitted,

10

John C. Freeman

PRELIMINARY AMENDMENT

The Commissioner for Patents
United States Patent and Trademark Office
35 Washington, D.C. 20231

Dear Sir:

This Preliminary Amendment is being presented to better describe Applicant's
40 claimed invention and it is believed does not present any new matter. Please amend the

specification and the claims as follows:

In the Specification:

On page 1 after the title and before line 4, insert the following new paragraphs and headings as follows:

5 Applicant claims, under 35 U.S.C. §§ 120 and 365, the benefit of priority of the filing date of September 21, 2000 of a Patent Cooperation Treaty patent application, copy attached, Serial Number PCT/EP00/09232, filed on the aforementioned date, the entire contents of which are incorporated herein by reference, wherein Patent Cooperation Treaty patent application Serial Number
10 PCT/EP00/09232 was not published under PCT Article 21(2) in English.

Applicant claims, under 35 U.S.C. § 119, the benefit of priority of the filing date of September 24, 1999 of a German patent application, copy attached, Serial Number 199 45 748.4, filed on the aforementioned date, the entire contents of which are incorporated herein by reference.

15 Background of the Invention

Field of the Invention

Replace the paragraph beginning on page 1, line 4 with the following paragraph:

The present invention relates to a method for determining at least one time
20 constant of a reference model in a cascaded controlling arrangement.

Replace the paragraph beginning at page 1, line 7 with the following heading and paragraph:

Description of the Related Art

Usually a cascaded controlling structure, including a position, rpm and current control device, is employed in numerically controlled machine tools. As a rule, the speed control device, which is connected downstream of the position control device, is embodied as a PI speed control device and includes a proportional branch (P) and an integral branch (I). The phase response of the upstream connected position control device worsens as a result of the effect of the integral branch of the speed control device. It is therefore necessary as a consequence of this to reduce the loop gain k_V of the position control device a priori in order to prevent oscillations in the drive systems of the machine tool controlled by the controlling device. However, as large as possible a loop gain k_V of the position control device is desired in principle.

Replace the paragraph beginning at page 1, line 29 with the following heading and paragraph:

SUMMARY AND OBJECTS OF THE INVENTION

It is therefore an object of the present invention to disclose a method for determining at least one time constant of a 2nd order reference model, which is arranged in a cascaded controlling device of a machine between a position control device and an speed control device, and which assures an optimized control behavior of the controlling device.

Replace the paragraph beginning on page 1, line 33 with the following paragraph:

This object is attained by a method for determining at least one time constant of a reference model, which is designed as a 2nd order time-delay element of a

machine. The method includes detecting an oscillation frequency of an undamped machine oscillation and determining an optimized value of a time constant of the reference model as a function of the detected oscillation frequency of the undamped machine oscillation.

5 Delete the paragraph beginning at page 1, line 35.

Replace the paragraph beginning on page 1, line 37 with the following paragraph:

The parameterization of a suitable 2nd order reference model for the most varied types of machines is now possible by the method of the present invention.

10 Here, the resulting reference model essentially always assures that at least the undesired influence of the integral portion of the speed control device on the control behavior is eliminated.

Between lines 2 and 3 of page 2, insert the following new paragraph:

It should be noted that the machine tools controlled in the past and by the
15 present invention can generally thought of as falling with one of two categories. One category or type of machine tool regards rigid machines that are not too large in structural size, which is mostly directly driven or has linear motors. A second category or type of machine tool regards machine tools with a dominant natural frequency in the range between 15 Hz to 80 Hz, in which no sufficiently large kV
20 factor can be set.

Replace the paragraph beginning on page 2, line 3 with the following paragraph:

Depending on the machine type, one time constant or two time constants are

Surprisingly, or contrary to theoretical reflections, it is now possible by the steps of the present invention for determining the time constant to also compensate controlled systems with idle times and delay elements for machines which theoretically would require higher order reference models; this applies in particular to the above mentioned category of non-rigid machines with dominant natural frequency. The determination of theoretically exact n th-order reference models ($n > 2$) in such machines would be connected with a very large outlay. In contrast to this it is possible by the use of second order time-delay elements as the reference model, whose time constants are determined in accordance with the present invention, to keep the resulting outlay for parameterization of the reference model low.

Replace the paragraph beginning on page 2, line 18 with the following paragraph:

The method in accordance with the present invention can be performed manually, as well as in an automated manner.

5

paragraph:

Further advantages, as well as details of the method in accordance with the present invention ensue from the subsequent description of exemplary embodiments by the attached drawings.

- 5 Replace the paragraph beginning at page 2, line 23, with the following paragraph:

Shown here are in:

Replace the paragraph beginning on page 2, line 24 with the following heading and paragraph:

10 BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 shows a block diagram representation of a part of an embodiment of a cascaded controlling structure of a numerically controlled machine tool in accordance with the present invention;

- 15 Replace the paragraph beginning at page 2, line 26 with the following paragraph:

FIGS. 2a and 2b show a flow diagram in each for explaining an embodiment of a method of the determination, in accordance with the present invention, of the time constant of a 2nd order reference model to be used with the cascaded controlling structure of FIG. 1;

- 20 Replace the paragraph beginning at page 2, line 28 with the following paragraph:

FIGS. 3 to 21, respectively, show different representations to be used with the cascaded controlling structure of FIG. 1, which will be explained in greater detail in

the ANNEX.

Before lines 29 and 30 at page 2, insert the following heading:

DESCRIPTION OF THE PREFERRED EMBODIMENT(S) OF THE INVENTION

Replace the paragraph beginning at page 2, line 33 with the following
5 paragraph:

The portion of the controlling structure represented includes a position control device 10, as well as a downstream- connected speed control device 20. The actual controlled system 30 is arranged downstream of the speed control device 20 and is only schematically indicated. In the present example, the speed control device is
10 embodied as a PI control device (proportional-integral control device); the integral branch 21, as well as the proportional branch 22 of the speed control device 20 are represented separately of each other in FIG. 1. A reference model 40 is arranged between the position control device 10 and the speed control device and is embodied as a 2nd order time-delay element, i.e. a so-called PT2 element. The reference model
15 40 simulates the behavior of the closed speed control device 20 without an integral portion and in this way assures that at least the undesired influence of the integral portion, or integral branch 21, on the control behavior of the speed control device is eliminated. As already indicated above, by the steps to be explained in what follows it is possible in a surprising manner to also parameterize reference models which
20 compensate controlled systems with idle times and delay elements. In theory it would be necessary to parameterize reference models with orders $n > 2$ for such controlled systems, which would be relatively expensive.

Replace the paragraph beginning at page 3, line 20 with the following

paragraph:

Contrary to theoretical considerations it is shown by the present invention that the use of 2nd order reference models, whose time constants T_1 and T_2 are determined in accordance with the present invention, is even possible when the
5 respective system would actually have to be simulated by a reference model of higher order n , i.e. $n > 2$. However, the mathematically exact representation of such a complex system by an appropriate n th order reference model would basically cause an extremely high computational effort. In actuality this has the result that by the use of a 2nd order reference model, whose time constants T_1 and T_2 are determined by
10 means of the invention, it is possible to also optimize the control behavior of the speed control device 20 for machines which are part of the second category already discussed above. Here, by employing a 2nd order reference model, which is parameterized in accordance with the present invention, in these systems, not only is the influence of the integral branch of the speed control device eliminated, but
15 moreover the influence of additional delays, or idle times, in the controlled system is also minimized. It is surprisingly possible to use loop gains k_V in such systems with 2nd order reference models parameterized in accordance with the present invention, which are greater than possible loop gains k_V in case of a non-existing, or switched off integral branch in the speed control device.

20 Replace the paragraph beginning at page 3, line 36 with the following paragraph:

The operation in accordance with the present invention for determining the time constants T_1 , T_2 for the 2nd order reference model will now be explained by the

adder 304. A momentary disturbance signal M_s is fed to the adder 304. As shown in FIG. 3, the adder 304 is connected to a control system 306 that generates the signal $G(s) = (\text{num}/\text{den})$ which is fed to a component 308 that generates a loss signal 310 that is a function of rpm. The loss signal 310 is fed back to the adder 304. The signal

5 $G(s)$ and the signal M_s are each fed to a second adder 312 that adds the two signals to generate signal 314. The signal 314 is then fed to an amplifier 316 to generate signal M_{sl} .

Between lines 12 and 13 at page 8, insert the following paragraph:

As shown in FIG. 4, the signal l_q is fed to a control system 400 with controlled

10 disturbance that is supplied by a momentary disturbance device 402. The control system generates a resultant signal nsi .

Between lines 22 and 24 at page 8, insert the following paragraphs:

As shown in FIG. 5, a jerk signal 500 is fed to a switch 502 along with an rpm

15 jerk signal 504 and a feedback signal 506. The switch 502 sends one of the three signals 500, 504, 506 to an amplifier 508 where the signal is multiplied to generate a resultant signal 510. The resultant signal 510 is sent to an adder 512, a reference model component 514 and a second switch 516. At the reference model component 514, the resultant signal 510 is operated by the factor $(2)/MP2500$ and the signal 518 is fed to the switch 516. The switch 516 selects one of the signals 518, 510 and a

20 reference model signal 520. The selected signal is sent to an adder 522 that adds the selected signal with a disturbance signal 524. The combined signal 526 is fed to component 528 that applies the factor $MP2510/s$ to generate signal 530 that is fed to adder 532 and multiplexer 534.

At the adder 512, the resultant signal 510 is added to the disturbance signal 524 to generate a signal 536 that is fed to amplifier 538 that multiplies the signal 536 by a factor that results in signal 540 that is later fed to adder 532 and multiplexer 534. The adder 532 generates a signal 541 that is fed to control system 542 that adjusts the
 5 signal 541 to take into account disturbance effects. The signal 524 output from the control system 542 is fed back to both adder 512 and adder 522. The signal 524 is also fed to an amplifier 546 that generates a signal 548 that is fed to multiplexer 550 and component 552 that applies the factor $1/s$. The signal 554 generated by component 552 is fed to amplifier 556 and the amplified signal 558 is fed to adder
 10 560.

A pulse generator 562 generates a signal that is operated by a point set point component 564 that applies a factor $1/s$ to generate signal 566. The signal 566 is fed to both adder 560, adder 568 and multiplexer 570. The adder 568 adds the signals 558 and 566 to generate signal 572 that is multiplied in amplifier 574 and the signal
 15 576 is fed to multiplexer 550. The adder 560 adds signals 558 and 566 to generate a signal that is amplified by amplifier 577 to generate feedback signal 506.

The multiplexer 570 generates a signal 578 that is fed to amplifier 580 and the signal 582 is fed to multiplexer 550. The multiplexer 550 sends its signal to a multiplexer 584 that also receives a signal from multiplexer 534. The multiplexer 584
 20 generates a signal 586 that is received by component 588 that is a MATLAB data file where all resulting simulation data results are stored and from which all graphs shown in FIGS. 6-12, 14-17 and 20 are extracted.

Between lines 33 and 34 at page 8, insert the following new paragraph:

Position control device amplification MP1510 [m/min/mm] = 15 P-factor
(speed control device)

Replace the paragraph beginning at page 10, line 30 with the following paragraph:

P-factor speed control device: in [As/U]
 Motor constant: kMC/sqrt(2) in [Nm/A]
 Moment of mass inertia of the system J_L

$$G(s) = MP2500 * k_{MC} * 1/(2 * \pi) * 1/(J_L * s)$$

$$k'_p = MP2500 * k_{MC} * 1/(2 * \pi)$$

$$5 \quad G(s) = k'_p * 1/([J_L] J_L * s)$$

The conversion function H(s) of the closed control loop is:

$$H(s) = G(s)/(1 + G(s))$$

$$H(s) = (k'_p / (J_L * s)) / (1 + (k'_p / (J_L * s)))$$

$$10 \quad H(s) = 1/(1 + (J_L * s)/k'_p)$$

$$H(s) = 1/(1 + T_1 * s)$$

A PT1 element with the time constant T1 is obtained as the IPC reference model:

15

$$T_1 = J_L/k'_p = (J_L * 2 * \pi) / (MP2500 * k_{MC}) \quad (F1)$$

Replace the paragraph beginning at page 11, line 31 with the following

20 paragraph:

Heidenhain controls have an acceleration feedforward control, which can be set by a machine parameter. This machine parameter MP26 provides the reciprocal value of the angular acceleration α per current in $[As^2/U]$. The time constant of the IPC can be calculated in a simple manner by the angular acceleration.

25 M_{el} = Electrical moment [Nm]

k_{MC} = Momentary motor constant [Nm/A]

J_L = Moment of mass inertia $[kgm^2]$

MP26 = Acceleration feedforward control $[As^2/U]$

30 $M_{el} = I_{MOT} * k_{MC}$

$\alpha = M_{el}/J_L$

35

$$\alpha = (I_{\text{MOT}} * 2 * \pi) / \text{MP26}$$

This is equal to:

$$J_L/k_{MC} = (MP26)/2 * \pi$$

This inserted in (F1):

$$T_1 = J_L/k_p' = (J_L * 2 * \pi) / (MP25 * k_{MC})$$

$T_1 = \text{MP26/MP25 (F2)}_1$

Between lines 33 and 35 at page 12, insert the following new paragraph:

Please note that the graphs shown in FIGS. 11 and 12 are known as Bode diagrams which are used to characterize the behavior of a filter. In particular, the upper graphs of FIGS. 11 and 12 show the amplitude/gain response of the filter. The lower graphs show the phase response of the filter. The x-axis represents the frequency over a certain range.

Between lines 16 and 18 at page 13, insert the following new paragraphs:

As shown in FIG. 13, a jerk signal 600 is fed to a switch 602 along with a speed feedforward control signal 604 and an rpm jerk signal 606. The switch 602 sends one of the three signals to an amplifier 608, which applies MP2020 to generate a signal 610 that is fed to the speed control system 612.

The speed control system 612 receives five other signals. One of the signals 614 is generated by the IPC component 616 and another of the signals is the jerk signal 600. The two other signals 622, 624 are initiated by interpolator 626 where the a_soll and w_soll signals from the interpolator are amplified by amplifiers 628, 630, respectively, that apply MO2020 to generate the resultant signals received by the control system 612.

The control system 612 generates a signal 632 that is received by a control system with disturbance introduction 634 whose output signal 636 is fed back to the control system 612 and a component 638 that applies $1/s$ to the signal which results in signal 640. Signal 640 is fed to an amplifier 642 that applies MP2020 to generate a signal 644 that is received by adder 646 that also receives a signal s_soll . The adder 644 combines the two signals to provide a signal 648 that is amplified via amplifier 649 and received by adder 650. The adder 650 sums the signal from amplifier 649 with a signal 652 that is the result of the amplification, via amplifier 654, of signal a_soll generated by the interpolator 626. The speed control signal 604 is then fed back to the switch 602.

As shown in FIG. 13, the signal s_soll is also fed to an amplifier 656 that sends the amplified signal to an adder 658 and a multiplexer 660. The adder 658 receives a signal 662 that is the result of the amplification of signal 644 via amplifier 664. The signal 662 is also sent to multiplexer 660. The multiplexer 660 and the adder 658, in combination with amplifier 666, send signals 668, 670 to a multiplexer 672. The multiplexer 672 also receives a signal 674 from an amplifier 676 that amplifies signal 636.

The multiplexer 672 generates a signal 678 that is fed to multiplexer 680. The multiplexer 676 also receives a signal 682 from the controller 612. The multiplexer 680 generates a signal 684 that is received by component 686 that is a MATLAB data file where all resulting simulation data results are stored and from which all graphs shown in FIGS. 6-12, 14-17 and 20 are extracted

Replace the paragraph beginning at page 13, line 20 with the following

Between lines 35 and 36 at page 14, insert the following new paragraphs:

As shown in FIG. 18, a resultant signal 700 is formed as the combination of the product of signals a_{soll} and T_1 being added to the signal n_{soll} . The resultant signal 700 is fed to the IPC 702 which generates a signal 704 that is added with the signal n_{ist} so as to form a signal 706. The signal 706 is then fed to an integral branch 708.

Replace the paragraph beginning at page 15, line 3 with the following

10 paragraph:

The IPC with acceleration and jerk control is represented in FIG. 19. As shown in FIG. 19, a resultant signal 800 is formed as the combination of the signals r_{soll} , T_r , a_{soll} , T_1 and n_{soll} so that resultant signal 800 is fed to the IPC 802 which generates a signal 804 that is added with the signal n_{ist} so as to form a signal 806.

15 The signal 806 is then fed to an integral branch 808 which in turn generates an output signal 810. The proportional branch 812 receives a signal 814 so as to generate an output signal 816 that is added with the output signal 810.

Replace the paragraph beginning at page 15, line 15 with the following paragraphs:

20 The structure of the speed control device block with feedforward control in the control device output is represented in FIG. 21. In particular, the structure includes six input signals 900, 902, 904, 906, 908, 910. The input signal 900 is fed to a switch 912. The input signal 906 is fed to an amplifier 914 where the amplified signal 916 is

fed to an IPC model feedforward control 918 that applies the factor $1/MP2500$. The resultant signal 920 is fed to switch 912. The switch 912 also receives a constant signal 922.

The signal 908 is fed to the IPC phase reference model control 924 that also
 5 applies the factor $1/MP2500$ so as to generate signal 926 that is fed to switch 928. The switch 928 also receives signal 908 and signal 930. The switch 928 chooses one of the three signals 908, 926 and 930 and feeds them to an adder 932 that also receives signal 910. The added signal 934 is sent to a component 936 that applies the factor $P2510/2*s$ so as to generate signal 938.

10 As shown in FIG. 21, the signal from the switch 912 and the signals 902 and 922 are sent to a switch 940 that sends one of the three signals to both adder 942 and adder 944. The adder 942 receives the signal from switch 940 and signal 938 and adds the two to generate signal 944 which is sent to multiplexer 946. The multiplexer 946 also receives signals 956 and 965 and sends a signal 966 to an output.

15 Signals 902, 922 and 948, which is the result of the amplification of signal 904 by amplifier 950 are sent to switch 952 where one of the three is sent to adder 944. The adder 944 receives two other signals 954 and 956. Signal 954 is the result of amplifying signal 910 by amplifier 958. Similarly, signal 956 is the result of amplifying signal 960 via amplifier 962. Signal 956 is the result of adding signals
 20 908 and 910 by adder 964. As shown in FIG. 21, the signals from the switches 940, 952 and signals 938, 954 and 956 are combined by adder 944 to generate signal 965 that is sent to an output.

After line 15 at page 19 insert the following new paragraph:

28. The method of claim 23, further comprising checking whether said second time constant provides an acceptable system behavior, or whether an optimization of said second time constant must be performed.

5 29. The method of claim 28, further comprising optimizing said second time constant by, proceeding from said starting value for said second time constant, changing said second time constant in steps until said undamped machine oscillation is registered, and a value of said optimized second time constant obtained therefrom is used as an optimized value for parameterizing said reference model.

10

30. The method of claim 29, further comprising:
using said optimized time constant and said second time constant; and
increasing said loop gain until an undamped machine oscillation is registered, and using an associated loop gain as a second maximum loop gain in
15 subsequent operation of said method.

31. The method of claim 1, wherein said method is exercised in an automated manner.

20 32. The method of claim 1, further comprising using in said machine said reference model with said optimized value of said time constant.

33. The method of claim 31, wherein said machine theoretically requires

an nth order reference model, wherein $n > 2$ applies.

34. A device for determining at least one time constant of a reference model, which is designed as a 2nd order time-delay element of a machine, said device
5 comprising:

a reference model arranged in a cascaded control arrangement;
a position control device with a loop gain;
a closed speed control device, which comprises a proportional branch and an
integral branch and wherein said reference model is located between said position
10 control device and said closed speed control device;

a detector for detecting an oscillation frequency of an undamped machine
oscillation; and

an optimizer that determines an optimized value of a time constant of said
reference model as a function of said detected oscillation frequency of said undamped
15 machine oscillation.

35. The device of claim 34, wherein said reference model at least
essentially simulates the behavior of said closed speed control circuit without taking
said integral portion into consideration.

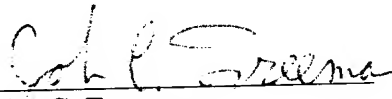

20

Please note that new claims 17-35 are being presented to provide additional
coverage regarding a measuring system. In addition, since the original claims reflect
a literal translation of the claims of the corresponding Patent Cooperation Treaty,

there is a need to stylize their language to everyday English and to use U.S. patent terminology. Accordingly, the cancellation of claims 1-16 and the addition of new claims 17-35 are not being presented for reasons of patentability as defined in Festo Corporation v. Shoketsu Kinzoku Kogyo Kabushiki Co., Ltd., 234 F.3d 558, 56

5 USPQ2d 1865 (Fed. Cir. 2000).

Marked up Version of Specification

The present invention relates to a method for determining at least one time constant of a reference model in a cascaded controlling arrangement [in accordance
5 with the preamble of claim 1].

Description of the Related Art

Usually a cascaded controlling structure, [consisting of] including a position, rpm and current control device, is employed in numerically controlled machine tools.
10 As a rule, the speed control device, which is connected downstream of the position control device, is embodied as a PI speed control device and [comprises] includes a proportional branch (P) and an integral branch (I). The phase response of the upstream connected position control device worsens as a result of the effect of the integral branch of the speed control device. It is therefore necessary as a consequence
15 of this to reduce the loop gain k_V of the position control device a priori in order to prevent oscillations in the drive systems of the machine tool controlled by the controlling device. However, as large as possible a loop gain k_V of the position control device is desired in principle.

20 SUMMARY AND OBJECTS OF THE INVENTION

It is therefore [the] an object of the present invention to disclose a method for determining at least one time constant of a 2nd order reference model, which is arranged in a cascaded controlling device of a machine between a position control device and an speed control device, and which assures an optimized control behavior

5

10

15

15

Further advantages, as well as details of the method in accordance with the present invention ensue from the subsequent description of exemplary embodiments by [means of] the attached drawings.

20 Shown here are in:

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1[,] shows a block diagram representation of a part of an embodiment of

a cascaded controlling structure of a numerically controlled machine tool in accordance with the present invention;[,]

FIGS. 2a and 2b[,] show a flow diagram in each for explaining an embodiment of a method of the determination, in accordance with the present invention, of the time constant of a 2nd order reference model to be used with the cascaded controlling structure of FIG. 1;[,]

FIGS. 3 to 21, respectively, show different representations to be used with the cascaded controlling structure of FIG. 1, which will be explained in greater detail in the ANNEX.

The portion of the controlling structure represented [comprises] includes a position control device 10, as well as a downstream- connected speed control device 20. The actual controlled system 30 is arranged downstream of the speed control device 20 and is only schematically indicated. In the present example, the speed control device is embodied as a PI control device (proportional-integral control device); the integral branch 21, as well as the proportional branch 22 of the speed control device 20 are represented separately of each other in FIG. 1. A reference model 40 is arranged between the position control device 10 and the speed control device and is embodied as a 2nd order time-delay element, i.e. a so-called PT2 element. The reference model 40 simulates the behavior of the closed speed control device 20 without an integral portion and in this way assures that at least the

surprisingly possible to use loop gains kV in such systems with 2nd order reference models parameterized in accordance with the present invention, which are greater than possible loop gains kV in case of a non-existing, or switched off integral branch in the speed control device.

5

The operation in accordance with the present invention for determining the time constants $T1$, $T2$ for the 2nd order reference model will now be explained by [means of] the flow diagrams in FIGS. 2a and 2b.

10

The theoretical considerations on which the present invention is based will be explained in greater detail in what follows in the following ANNEX and several simulations and test results will be presented.

15

The method of the present invention and the arrangement of the present invention were tested by [means of] a mathematical simulation. This simulation which, besides the mathematical machine model, also contains the mathematical model of the present invention, will be described in what follows.

20

The mass inertia moment of the controlled system, together with the momentary constants of the motor, are the defining characteristics of the system. The following parameters are used in connection with this:

Mass inertia $[J_I] J_L = 50 \text{ kgcm}^2$

Motor constant $k_{MC} = (1.5/2) * (Nm/A_{eff})$, wherein A_{eff} is known in the art to

represent an effective motor current which is measured in Amperes

Therefore, the controlled system $G(s)$ is determined by:

$$G(s) = (\text{num}/\text{den}) = 1/(J_L * s)$$

5 The conversion from the radian frequency ω to U/s (U represents the number of rotations) takes place by [means of] a downstream-connected P-element with $1/(2 * \pi)$. A disturbance can be introduced via the input "momentary disturbance M_s ", which simultaneously affects the momentary value and the actual rpm. This is intended to correspond to a typical disturbance because of a milling cutter action and
10 is used to rate the disturbance rigidity.

For simulating realistic rpm-connected losses, a derivative feedback k'_p of the internal system output to the momentary summing point takes place. By [means of] this a new controlled system $G'(s)$ is created:

$$G'(s) = (1/(J_L * s))/(1 + k'_p/(J_L * s))$$

15 $G'(s) = 1/(k'_p + (J_L * s))$

$$G'(s) = 1/k'_p * 1/(1 + (J_L/k'_p * s))$$

A TPI control device is created by [means of] this derivative feedback.

20 A model of the 1st order controlled system with disturbance introduction is represented in FIG. 3. As shown in FIG. 3, a signal l_q is fed to an amplifier 300 that multiplies the signal l_q by a momentary constant to generate a signal 302 that is fed to adder 304. A momentary disturbance signal M_s is fed to the adder 304. As shown in

FIG. 3, the adder 304 is connected to a control system 306 that generates the signal $G(s) = (\text{num/den})$ which is fed to a component 308 that generates a loss signal 310 that is a function of rpm. The loss signal 310 is fed back to the adder 304. The signal $G(s)$ and the signal M_s are each fed to a second adder 312 that adds the two signals to generate signal 314. The signal 314 is then fed to an amplifier 316 to generate signal M_{sl} .

Position control device amplification MP1510 $[[\text{m/min/mm}]] \frac{\text{m/min/mm}}{\text{m/min/mm}} = 15$

P-factor (speed control device)

10 MP2500 $[[\text{As}]] \frac{[\text{As}]}{[\text{A}]} = 9$ I-factor (speed control device) MP2510 $[[\text{A}]] \frac{[\text{A}]}{[\text{A}]} = 2200$, wherein A represents Amperes.

The following physical values appear in this closes control loop:

15 P-factor speed control device: in $[[\text{As/U}]] \frac{[\text{As/U}]}{[\text{A}]}$
 Motor constant: $k_{MC}/\sqrt{2}$ in $[[\text{Nm/A}]] \frac{[\text{Nm/A}]}{[\text{A}]}$
 Moment of mass inertia of the system $[J_I] \frac{J_L}{J_I}$

20 Thus, the conversion function $G(s)$ of the open control loop is:

$$G(s) = \text{MP2500} * k_{MC} * 1/(2 * \pi) * 1/([J_I] \frac{J_L}{J_I} * s)$$

25 $k'_p = \text{MP2500} * k_{MC} * 1/(2 * \pi)$

$$G(s) = k'_p * 1/([J_I] \frac{J_L}{J_I} * s)$$

30 The conversion function $H(s)$ of the closed control loop is:

$$H(s) = G(s)/(1 + G(s))$$

$$H(s) = (k'_p / ([J_I] J_L * s)) / (1 + (k'_p / ([J_I] J_L) * s))$$

$$H(s) = 1 / (1 + ([J_I] J_L * s) / [K] k'_p)$$

$$H(s) = 1 / (1 + T_1 * s)$$

5 A PT1 element with the time constant T1 is obtained as the IPC reference model:

10
$$T_1 = [J_I] J_L / k'_p = ([J_I] J_L * 2 * \pi) / (MP2500 * k_{MC}) \quad (F1)$$

Heidenhain controls have an acceleration feedforward control, which can be set by [means of] a machine parameter. This machine parameter MP26 provides the reciprocal value of the angular acceleration α per current in $[[As^2/U]]$ $[As^2/U]$. The
15 time constant of the IPC can be calculated in a simple manner by [means of] the angular acceleration.

M_{el} = Electrical moment $[[Nm]]$ $[Nm]$

k_{MC} = Momentary motor constant $[[Nm/A]]$ $[Nm/A]$

$[J_I] J_L$ = Moment of mass inertia $[[kg.m^2]]$ $[kgm^2]$

20 $MP26$ = Acceleration feedforward control $[[As^2/U]]$ $[As^2/U]$

$$M_{el} = I_{MOT} * k_{MC}$$

25
$$\alpha = M_{el} / [J_I] J_L$$

$$\alpha = (I_{MOT} * 2 * \pi) / MP26$$

30 This is equal to:

$$[J_I] J_L / k_{MC} = (MP26) / 2 * \pi$$

35 This inserted in (F1):

$$T_1 = [J_I] J_L / k'_p = ([J_I] J_L * 2 * \pi) / (MP25 * k_{MC})$$

$$T_1 = MP26/MP25 (F2)$$

5

In what follows, the various feedforward controls are sequentially switched in.

To compare the effects, all simulation parameters were kept constant.

System Parameters:

$$\text{Momentary constant } [Ktc[Nm/A]] \underline{Ktc[Nm/A]} = 1.5 * \text{sqrt}(2)$$

10

$$\text{Momentary load inertia } [Jl [kg.m^2]] \underline{Jl[kgm^2]} = 9$$

$$\text{Rpm losses } [[Nm/\omega]] \underline{Nm/\omega} = 0.15$$

Control device circuit parameters:

$$\text{Position control device amplification MP1510 } [[m/min/mm]] \underline{m/min/mm} = 9$$

$$\text{P-factor (speed control device) MP2500 } [[As]] \underline{As} = 9$$

15

$$\text{I-factor (speed control device) MP2510 } [[A]] \underline{A} = 2200$$

Interpolation parameters:

$$\text{Jerk } r [[m/s^3]] \underline{[m/s^3]} = 2 * [103] \underline{10^3}$$

$$\text{Acceleration } a [[m/s^2]] \underline{[m/s^2]} = 5$$

$$\text{Speed } v [[m/s]] \underline{[m/s]} = 0.4 / 60$$

20

$$\text{Position } s [[m]] \underline{[m]} = 4 * [10-4] \underline{10^{-4}}$$

The resulting following error without feedforward controls is represented in FIG. 14. A maximum following error of approximately 45 [μm] $\underline{\mu m}$ results, which is impermissibly high.

25

The resulting following error without feedforward controls is represented in

FIG. 15. A maximum following error during the acceleration phase of 10 [um] μm results.

The IPC with acceleration and jerk control is represented in FIG. 19. As
 5 shown in FIG. 19, a resultant signal 800 is formed as the combination of the signals
 r_{soll} , T_r , a_{soll} , T_1 and n_{soll} so that resultant signal 800 is fed to the IPC 802 which
generates a signal 804 that is added with the signal n_{ist} so as to form a signal 806.
The signal 806 is then fed to an integral branch 808 which in turn generates an output
signal 810. The proportional branch 812 receives a signal 814 so as to generate an
 10 output signal 816 that is added with the output signal 810.

The structure of the speed control device block with feedforward control in the
 control device output is represented in FIG. 21. In particular, the structure includes
six input signals 900, 902, 904, 906, 908, 910. The input signal 900 is fed to a switch
 15 912. The input signal 906 is fed to an amplifier 914 where the amplified signal 916 is
fed to an IPC model feedforward control 918 that applies the factor $1/MP2500$. The
resultant signal 920 is fed to switch 912. The switch 912 also receives a constant
signal 922.

The signal 908 is fed to the IPC phase reference model control 924 that also
 20 applies the factor $1/MP2500$ so as to generate signal 926 that is fed to switch 928.
The switch 928 also receives signal 908 and signal 930. The switch 928 chooses one
of the three signals 908, 926 and 930 and feeds them to an adder 932 that also
receives signal 910. The added signal 934 is sent to a component 936 that applies the

factor $P2510/2*s$ so as to generate signal 938.

As shown in FIG. 21, the signal from the switch 912 and the signals 902 and 922 are sent to a switch 940 that sends one of the three signals to both adder 942 and adder 944. The adder 942 receives the signal from switch 940 and signal 938 and
 5 adds the two to generate signal 944 which is sent to multiplexer 946. The multiplexer 946 also receives signals 956 and 965 and sends a signal 966 to an output.

Signals 902, 922 and 948, which is the result of the amplification of signal 904 by amplifier 950 are sent to switch 952 where one of the three is sent to adder 944. The adder 944 receives two other signals 954 and 956. Signal 954 is the result of
 10 amplifying signal 910 by amplifier 958. Similarly, signal 956 is the result of amplifying signal 960 via amplifier 962. Signal 956 is the result of adding signals 908 and 910 by adder 964. As shown in FIG. 21, the signals from the switches 940, 952 and signals 938, 954 and 956 are combined by adder 944 to generate signal 965 that is sent to an output.

(54) Title: METHOD FOR DETERMINING TIME CONSTANTS OF A REFERENCE MODEL IN A CASCADE REGULATING CIRCUIT

(54) Bezeichnung: VERFAHREN ZUR ERMITTLUNG VON ZEITKONSTANTEN EINES REFERENZMODELLES IN EINER KASKADIERTEN REGELUNGSANORDNUNG

(57) Abstract: The invention relates to a method for determining at least one time constant of a reference model which is located in a regulating circuit of a machine positioned between a position regulator having an amplification factor k_V and a rotation speed regulator. Said rotation speed regulator comprises a proportional branch and an integral branch. The reference model is embodied as a 2nd order delay member and essentially reproduces at least the behavior of the closed regulating circuit without taking into account an integral component. An optimized value of a time constant pertaining to the reference model is determined and depends on a detected vibration frequency of non-shock absorbed machine vibrations.

(57) Zusammenfassung: Es wird ein Verfahren zur Ermittlung von mindestens einer Zeitkonstanten eines Referenzmodelles angegeben, das in einer kaskadierten Regelungsanordnung einer Maschine zwischen einem Lageregler mit einem Verstärkungsfaktor k_V und einem Drehzahlregler angeordnet ist. METHOD FOR DETERMINING TIME CONSTANTS OF A REFERENCE
MODEL IN A CASCADE CONTROLLING CIRCUIT

The present invention relates to a method for determining at least one time constant of a reference model in a cascaded controlling arrangement in accordance with the preamble of claim 1.

Usually a cascaded controlling structure, consisting of a position, rpm and current control device, is employed in numerically controlled machine tools. As a rule, the speed control device, which is connected downstream of the position control device, is embodied as a PI speed control device and comprises a proportional branch (P) and an integral branch (I). The phase response of the upstream connected position control device worsens as a result of the effect of the integral branch of the speed control device. It is therefore necessary as a consequence of this to reduce the loop gain k_V of the position control device a priori in order to prevent oscillations in the drive systems of the machine tool controlled by the controlling device. However, as large as possible a loop gain k_V of the position control device is desired in principle.

To solve these problems, it has already been suggested by P. Ernst and G. Heinemann in the course of a seminar presentation under the title "Optimierte Achsregelung mit durchgängig offenen CNC-Steuerungen" [Optimized Axis Control with Continuously Open CNC Controls] (ISW Position Controlling Seminar 1999, 26, 03/27/1999) in Chapter 2.2 to connect a reference model upstream of the speed control device. The reference model, designed as a 2nd order time-delay element, is matched to the behavior of the closed speed control device without an integral portion. It is possible in this way to eliminate, or at least to minimize, the detrimental influence of the integral portion on the control behavior of the speed control device. However, the desired elimination of disturbances without integral portions continues to be fully maintained. However, no further suggestions can be found in the cited reference regarding suitable parameterization, in particular the determination of suitable time constants, of a corresponding 2nd order reference model.

It is therefore the object of the present invention to disclose a method for determining at least one time constant of a 2nd order reference model, which is arranged in a cascaded controlling device of a machine between a position control device and a speed control device, and which assures an optimized control behavior of the controlling device.

This object is attained by a method having the features of the characterizing portion of claim 1.

Advantageous embodiments of the method in accordance with the invention ensue from the steps in the dependent claims.

The parameterization of a suitable 2nd order reference model for the most varied types of machines is now possible by means of the method of the invention. Here, the resulting

reference model always assures that at least the undesired influence of the integral portion of the speed control device on the control behavior is eliminated.

Depending on the machine type, one time constant or two time constants are determined in accordance with the invention, which determine the behavior of the reference
 5 model and therefore affect the control behavior of the controlling arrangement during the actual controlling operation. However, in accordance with the invention at least the so-called second time constant of the reference model is basically determined as a function of a detected oscillation frequency of a continuous machine oscillation.

Surprisingly, or contrary to theoretical reflections, it is now possible by means of the
 10 steps of the invention for determining the time constant to also compensate controlled systems with idle times and delay elements for machines which theoretically would require higher order reference models; this applies in particular to the above mentioned category of non-rigid machines with dominant natural frequency. The determination of theoretically exact n th-order reference models ($n > 2$) in such machines would be connected with a very large outlay. In
 15 contrast to this it is possible by means of the use of second order time-delay elements as the reference model, whose time constants are determined in accordance with the invention, to keep the resulting outlay for parameterization of the reference model low.

The method in accordance with the invention can be performed manually, as well as in an automated manner.

20 Further advantages, as well as details of the method in accordance with the invention ensue from the subsequent description of exemplary embodiments by means of the attached drawings.

Shown here are in

FIG. 1, a block diagram representation of a part of a cascaded controlling structure of a
 25 numerically controlled machine tool,

FIGS. 2a and 2b, a flow diagram in each for explaining the determination in accordance with the invention of the time constant of a 2nd order reference model,

FIGS. 3 to 21, respectively different representations, which will be explained in greater detail in the ANNEX.

30 In a greatly schematized form, FIG. 1 shows a block diagram representation of a part of a cascaded controlling structure of a numerically controlled machine tool, such as is known, for example, in a similar shape from the above discussed reference.

The portion of the controlling structure represented comprises a position control device 10, as well as a downstream- connected speed control device 20. The actual controlled system
 35 30 is arranged downstream of the speed control device 20 and is only schematically indicated. In the present example, the speed control device is embodied as a PI control device (proportional-integral control device); the integral branch 21, as well as the proportional branch

22 of the speed control device 20 are represented separately of each other in FIG. 1. A reference model 40 is arranged between the position control device 10 and the speed control device and is embodied as a 2nd order time-delay element, i.e. a so-called PT2 element. The reference model 40 simulates the behavior of the closed speed control device 20 without an integral portion and in this way assures that at least the undesired influence of the integral portion, or integral branch 21, on the control behavior of the speed control device is eliminated. As already indicated above, by means of the steps to be explained in what follows it is possible in a surprising manner to also parameterize reference models which compensate controlled systems with idle times and delay elements. In theory it would be necessary to parameterize reference models with orders $n > 2$ for such controlled systems, which would be relatively expensive.

The transfer function $H(s)$ of the reference model 40 embodied as a 2nd order time-delay element results in a known manner from the following equation (1):

$$H(s) = K / (1 + T1 * s + (T2)^2 * s^2) \quad \text{Equ. (1)}$$

The two time constants $T1$ and $T2$ are decisive for the layout, or the parameterization of the reference model 40. They must be determined as a function of the respective machine, or of the controlling conditions.

Contrary to theoretical considerations it has now been shown that the use of 2nd order reference models, whose time constants $T1$ and $T2$ are determined in accordance with the invention, is even possible when the respective system would actually have to be simulated by means of a reference model of higher order n , i.e. $n > 2$. However, the mathematically exact representation of such a complex system by means of an appropriate n th order reference model would basically cause an extremely high computational effort. In actuality this has the result that by means of the use of a 2nd order reference model, whose time constants $T1$ and $T2$ are determined by means of the invention, it is possible to also optimize the control behavior of the speed control device 20 for machines which are part of the second category already discussed above. Here, by employing a 2nd order reference model, which was parameterized in accordance with the invention, in these systems, not only is the influence of the integral branch of the speed control device eliminated, but moreover the influence of additional delays, or idle times, in the controlled system is also minimized. It is surprisingly possible to use loop gains kV in such systems with 2nd order reference models parameterized in accordance with the invention, which are greater than possible loop gains kV in case of a non-existing, or switched off integral branch in the speed control device.

The operation in accordance with the invention for determining the time constants $T1$, $T2$ for the 2nd order reference model will now be explained by means of the flow diagrams in

FIGS. 2a and 2b.

In the first part of the method explained in what follows, represented in FIG. 2a, first the time constant T2, or a correspondingly optimized value T2_OPT of the second time constant T2 will be determined.

5 In a first method step S10, first the determination, or presetting, of starting values T1_01 and T2_01 for the first and second time constant T1, T2 takes place. In the present example, the starting values T1_01 and T2_01 equaling T1_01 = 0 and T2_01 = 0 are selected. This selection of the starting values T1_01 and T2_01 equaling T1_01 = 0 and T2_01 = 0 means
10 for the entire system in the end that the 2nd order reference model is switched out of the controlling arrangement, or is not active.

In what follows, the loop gain kV of the position control device is increased in steps in the following steps S20 and S30 and a check is made after each increase to determine whether an oscillation in the respective machine is already recognizable. This takes place until at a first maximum loop gain kV_{max1} an almost undamped oscillation of the machine at a defined
15 oscillation frequency f_{s1} can be registered.

If an appropriate undamped oscillation of the machine can be registered, the associated oscillation frequency f_{s1} is measured, or determined, in accordance with the method step S40.

Thereafter, in the method step S50, the two optimized values T2_OPT and T1_OPT can be determined for the two time constants T1, T2. Here, the optimized value T2_OPT for the
20 second time constant T2 can be determined as a function of the oscillation frequency f_{s1} determined in step S40, i.e.

$$T2_OPT = f(f_{s1}) = 1 / (2 * \pi * f_{s1}) \quad \text{Equ. (2)}$$

25 The optimized value T1_OPT for the first time constant T1 results from predetermined system parameters in accordance with the following equation:

$$T1_OPT = (J_L * 2 * \pi) / (k_p * K_{MC}) \quad \text{Equ. (3)}$$

30 wherein J_L: Momentary load,

k_p: Loop gain of the proportional branch of the speed control device,

K_{MC}: Motor constant.

35 Subsequently a check is performed in method steps S60 to S85 whether the previously determined time constants T1, T2 of the 2nd order reference model assure the desired control behavior during the controlling operation. Moreover, a maximum loop gain kV of the position

control device for the optimized time constants $T1_OPT$, $T2_OPT$ is set in these method steps.

For this purpose, initially a check is made in the method step S60 whether an undamped oscillation of the machine results in the system when using the previously determined optimized values $T1_OPT$, $T2_OPT$ and the first maximum loop gain kV_{max1} determined in step S30.

If this is not the case, the loop gain kV is increased by steps in method steps S70 and S80 until an undamped machine oscillation can be registered at a loop gain kV_{max2} . The maximum loop gain kV_{max2} determined in this way at which, in connection with the time constants $T1_OPT$, $T2_OPT$ of the 2nd order reference model, an undamped machine oscillation occurs, is subsequently multiplied by a safety factor $K < 1$ in method step S85. From this then results the optimized loop gain kV_OPT for the position control device, which can be used for a stable system during controlling operations, i.e.

$$kV_OPT = K * kV_{max2} \quad (\text{Equ. 4})$$

The safety factor K can be selected as $K = 0.6$, for example, in order to assure sufficient stability of the position control device in this way.

However, if it is found in method step S60 that, when using the previously optimized time constants $T1_OPT$, $T2_OPT$ in the reference model and the loop gain kV_{max1} , an undamped machine oscillation already results at an oscillation frequency f_{s2} , the oscillation frequency f_{s2} is determined and an optimized time constant $T2_OPT$ is again determined in method step S65 as a function of the oscillation frequency f_{s2} in accordance with

$$T2_OPT = f(f_{s2}) = 1 / (2 * \pi * f_{s2}) \quad (\text{Equ. 2}).$$

If required, the determination of an optimized time constant $T2_OPT$ is repeated several times in method steps S60 and S65, until finally no undamped machine oscillation can be registered at the selected parameters of $T1_OPT$, $T2_OPT$.

In connection with machines of the first category, the second order reference model is basically parameterized after these steps, i.e. the two time constants $T1$ and $T2$ are determined. If it is intended to optimize the control structure of a machine of the second category, further method steps are required for suitably determining the first time constant $T1$ of the reference model in particular. This will be explained in what follows by means of FIG. 2b.

It is of course also possible to perform the following steps for determining a suitable first time constant $T1$ even with the mentioned machines of the first category in order to check in this way whether the value for $T1_OPT$ set in accordance with the above Equ. (3) provides an acceptable system behavior.

Thus, for determining an optimized value $T1_OPT'$ of the first time constant $T1$, first a second start value $T1_02$ for the first time constant $T1$ is set in method step S90. For this, the value for $T1$ determined in step S50 in accordance with Equ. (3) is used as the second start value $T1_02$, i.e. $T1_02 = T1_OPT$.

Thereafter the first time constant $T1$ is changed in method step S100, for example increased, and a check is subsequently made in method step S120 whether an undamped machine oscillation can already again be registered. Besides the increase of the first time constant $T1$ in step S100 it would basically also be conceivable that it be decreased.

As long as no undamped machine oscillation can be registered, the loop gain kV is increased in method steps kV up to a loop gain kV_{max3} , at which an undamped machine oscillation can be registered.

A check is thereupon made in method step S130, whether the loop gain kV_{max3} determined in this way is greater than the loop gain kV_{max2} , which had been maximal up to this time.

If the loop gain kV_{max3} is greater than the loop gain kV_{max2} , which had been maximal up to this time, the loop gain kV_{max3} is set to equal kV_{max2} , and a run-through of the method steps starting with S100 takes place again. This means that a check is made in the end whether with a changed value for $T1_OPT$ a higher value for the loop gain kV can possibly be set.

This takes place until in method step S130 it is determined that the loop gain kV_{max3} is no longer greater than the loop gain kV_{max2} determined during the previous run-through.

In accordance with method step S140, the value for the first time constant $T1$ then present, besides the already previously determined value $T2_OPT$, is used as the optimized value $T1_OPT$ for parameterizing the 2nd order reference model.

Furthermore, similar to the procedure in FIG. 2a, the last determined maximum loop gain kV_{max2} is multiplied by a correction factor $K < 1$, in order to again assure the stability of the position control device, i.e. the optimized value kV_OPT for the loop gain of the position control device again results as

$$kV_OPT = K * kV_{max2} \quad \text{Equ. (5)}$$

Thus, besides the two determined parameters $T1$ and $T2$ for the 2nd order reference model to be used, there is now also an optimized maximum loop gain kV_OPT for the position control device, which can be used in the subsequent controlling operation.

Alternative forms of embodiment also exist within the scope of the present invention.

The theoretical considerations on which the invention is based will be explained in greater detail in what follows in the following ANNEX and several simulations and test results will be presented.

ANNEX

(Theory, Simulation and Test Results)

5

1. Simulation with a Simplified Controlling Model

1.1 Model of the Controlled System

10

The method of the invention and the arrangement of the invention were tested by means of a mathematical simulation. This simulation which, besides the mathematical machine model, also contains the mathematical model of the invention, will be described in what follows.

15

The mass inertia moment of the controlled system, together with the momentary constants of the motor, are the defining characteristics of the system. The following parameters are used in connection with this:

20

Mass inertia $J_1 = 50 \text{ kgcm}^2$

Motor constant $k_{MC} = (1.5/2) * (\text{Nm}/A_{\text{eff}})$

25

Therefore, the controlled system $G(s)$ is determined by:

$$G(s) = (\text{num}/\text{den}) = 1/(J * s)$$

30

The conversion from the radian frequency ω to U/s takes place by means of a downstream-connected P-element with $1/(2 * \pi)$. A disturbance can be introduced via the input "momentary disturbance M_s ", which simultaneously affects the momentary value and the actual rpm. This is intended to correspond to a typical disturbance because of a milling cutter action and is used to rate the disturbance rigidity.

35

For simulating realistic rpm-connected losses, a derivative feedback k'_p of the internal system output to the momentary summing point takes place. By means of this a new controlled system $G'(s)$ is created:

40

$$G'(s) = (1/(J * s)) / (1 + k'_p * (1/(J * s)))$$

45

$$G'(s) = (1/(k'_p + (J * s)))$$

$$G'(s) = 1/k'_p * 1/(1 + (J/k'_p * s))$$

A TP1 control device is created by means of this derivative feedback.

A model of the 1st order controlled system with disturbance introduction is represented in FIG. 3.

1.2 Model of the Disturbed Controlled System

A model of the disturbed controlled system is represented in schematic form in FIG. 4. The controlled system is charged with a disturbance pulse of 2 Nm and of a length of 70 ms. The start time lies at 40 ms.

This disturbed controlled system is integrated into a simulation as a group "disturbed controlled system A -> U/s".

1.3 Simulation Model

The simulation model contains a closed position control device loop. For alignment purposes of the speed control device it is possible to introduce a skip of 200 mm/min to the speed control device via a switch 1. A suitable simulation model for examining a 1st order reference model is represented in FIG. 5. The IPC reference model can be switched on and off with the switch upstream of Sum 1.

2. Determination of the Simulation Parameters

It was necessary to determine the control device amplifications for parameterizing the control devices.

2.1 Alignment of the Speed Control device

For the alignment of the speed control device the disturbance moment of the controlled system was temporarily set to 0, and the switch 1 was set to skip. The skip size was 200 mm/min.

The conditions represented in FIG. 6 resulted for the loop gains for

P-factor (speed control device) = 9

I-factor (speed control device) = 2200

of the control device.

The simulation results correspond to a real drive mechanism. The control start time was set as $T_a = 4.6$ ms.

5 2.2 Determination of the Position Control Device Amplification k_V

To determine the maximum position control device amplification, the I-portion of the speed control device was set to 0.

10	Position control device amplification	= 15
	P-factor (speed control device)	= 9
	I-factor (speed control device)	= 0

The kV factor was set such that no oscillation of the actual motor current I_q occurred.

15 The low disturbance rigidity without the I-portion can be seen from the contour variation curve in FIG. 7. No complete removal of the disturbance takes place.

2.3 Activating the I-Portion of the Speed Control Device

20 The I-portion of the speed control device was activated without the position control
device amplification being reduced.

	Position control device amplification	= 15
	P-factor (speed control device)	= 9
25	I-factor (speed control device)	= 2200

In accordance with FIG. 8 it can be easily seen from the motor currents that the system oscillates. The kV factor (or the I-portion of the speed control device) must be reduced.

30 2.4 Reduction of the Position Control Device Amplification

The kV factor of the position control device was reduced until there was no longer a tendency to oscillate.

35	Position control device amplification	= 9
	P-factor (speed control device)	= 9
	I-factor (speed control device)	= 2200

The contour variation increases (bad control behavior) because of the smaller kV factor, but the disturbance rigidity is improved in comparison with a system without an I-portion (see FIG. 9).

5

2.5 Series-Connection of the IPC Reference Model (1st Order) with the I-Portion

The kV factor, which in the beginning had been possible without the I-portion of the speed control device, was set. In addition, the I-portion of the aligned speed control device was set. The reference model was realized in the 1st order (neglecting the derivative loss feedback of the controlled system).

10

Position control device amplification MP1510 [m/min/mm] = 15 P-factor (speed control device)

15

MP2500 [As] = 9 I-factor (speed control device) MP2510 [A] = 2200

It is possible to read out of the diagram in FIG. 10, that with a low contour variation a large disturbance rigidity is provided.

20

3. Calculation of the IPC Reference Model

The basis for the reference model is that all portions of the P control device, including the system, do not reach the integrator. Therefore a simplified model of the closed control loop (only the P control device is active) was inserted into the set point default of the integrator. The motor losses are not considered.

25

3.1 Calculation from Model Parameters

30

The following physical values appear in this closed control loop:

P-factor speed control device: in [As/U]

Motor constant: $k_{MC}/\sqrt{2}$ in [Nm/A]

Moment of mass inertia of the system J_I

35

Thus, the conversion function $G(s)$ of the open control loop is:

$$G(s) = MP2500 * k_{MC} * 1/(2 * \pi) * 1/(J_I * s)$$

Switching the feedforward control on or off

Acceleration feedforward control from the interpolator (IPO)

Speed feedforward control from the IPO

Set point rpm

5 Actual rpm.

The speed control block has the following outputs:

Three signals (via a multiplexer) for monitoring the currents in the speed control device

Momentary current output I_q of the speed control device.

10 The structure of the position control device simulation with feedforward control is represented in FIG. 13. The speed feedforward control (Sum6) had additionally been integrated into the position control circuit.

By connecting the disturbance moment with the appropriate input of the controlled system, a disturbance can act as before on the controlled system.

15 The system allowance comes from the interpolator block (IPO). It is possible to perform a parameterization of jerk, acceleration, speed and distance via the Matlab dataset "M_IPO.M". "M_IPO.M" is also called up within "M_IPC.M".

5.1 Simulations of Following Errors

20 In what follows, the various feedforward controls are sequentially switched in. To compare the effects, all simulation parameters were kept constant.

System Parameters:

25 Momentary constant $K_{tc}[\text{Nm/A}] = 1.5 * \text{sqrt}(2)$

Momentary load inertia $J_l[\text{kg.m}^2] = 9$

Rpm losses $[\text{Nm}/\omega] = 0.15$

Control device circuit parameters:

30 Position control device amplification MP1510 $[\text{m}/\text{min}/\text{mm}] = 9$

P-factor (speed control device) MP2500 $[\text{As}] = 9$

I-factor (speed control device) MP2510 $[\text{A}] = 2200$

35 Interpolation parameters:

Jerk $r[\text{m}/\text{s}^3] = 2 * 10^3$

Acceleration	$a \text{ [m/s}^2]$	$= 5$
Speed	$v \text{ [m/s]}$	$= 0.4 / 60$
Position	$s \text{ [m]}$	$= 4 * 10^{-4}$

5 5.1.1 Following Error without Feedforward Control

The resulting following error without feedforward controls is represented in FIG. 14. A maximum following error of approximately 45 μm results, which is impermissibly high.

10 5.1.2 Following Error with Speed Feedforward Control

The resulting following error without feedforward controls is represented in FIG. 15. A maximum following error during the acceleration phase of 10 μm results.

15 5.1.3 Following Error with Acceleration Feedforward Control

The resulting following error with acceleration feedforward control is represented in FIG. 16. As can be seen, no following error can be shown.

20 5.1.4 Following Error with IPC (without IPC feedforward control)

The resulting following error with feedforward control and IPC (without IPC feedforward control) is represented in FIG. 17. As can be seen, a following error of 13 μm is built up at the end of the acceleration phase.

25

5.2 Installation of an IPC Feedforward Control into the Speed Control device

To reduce the following error during the acceleration phase it is necessary to implement an acceleration feedforward control. Since the input value of the IPC is a speed, a multiplication of the acceleration feedforward control $a_{\text{soll(ipo)}}$ with the time constant T_1 is necessary.

To make possible an implementation with optimized computing time, the feedforward control summing point was moved ahead from the control device output to the IPC input, the structure represented in FIG. 18 results in the process, i.e. IPC with acceleration feedforward control.

35

A further correction of the following error can be achieved by means of a jerk feedforward control. The feedforward control value " $r_{\text{soll(ipo)}}$ " can be formed in the speed

The time constant T2 is calculated as follows:

$$T_2 = T_1 / (2 * D)$$

Clearly improved results were already achieved with the use of a 2nd order IPC, however, they still did not approach the results of the simulation, which lead to conclusions of a theoretical increase of the position control amplification kv of approximately 170%. The following time constants were determined for the DIGMA 700:

Time Constants at DIGMA 700:

	X-axis	Y-axis	Z-axis
MP25	15	15	12
MP26	0.0212	0.0205	0.0165
T1'	1	1	1
T2'	0.0017	0.0018	0.0018
T1	1.41 ms	1.37 ms	1.37 ms
T2	1.7 ms	1.8 ms	1.8 ms
D	0.41	0.39	0.38

The below table shows the position control amplifications (kV factors) achieved at the X-axis of the DIGMA 700 in connection with various IPC designs. A search for the oscillation threshold was always performed here. In accordance with a rule of thumb, the latter must always be multiplied by a factor of 0.65 for stable operations.

	kV (Oscillation limit)	kV (stable)
Without IPC	8.5	5.5
1st order IPC	9.5	6.2
2nd order IPC (D=0.5)	13.0	8.5
2nd order IPC (D=0.41)	14.5	9.5

Thus, the position control amplification could be increased to 170%.

6.2 Derivation of the IPC Algorithm

The derivation of the IPC algorithm is based on the equation:

$$H(s) = 1 / (1 + (T1 * s) + (T2^2 * s^2))$$

Determination of the T2 Time Constant

5

Tests with DIGMA 700 have shown that the T2 time constant, and therefore damping, is optimally set when the following error in the jerk phase showed a minimal deviation (with integrated jerk feedforward control). It was possible in this way to determine the T2 time constant for all three axes.

10

In the lab set-up (JL directly on the motor shaft) it was also possible to perform the determination of the optimum T2 time constant in this way.

Connection between Damping and T2 Time Constant

15

$$D = T1 / (2 * T2)$$

6.3 Employment in Machines with Dominant Natural Frequency

20

A further employment option of the IPC is provided when in connection with machines with low natural resonance and insufficient damping the IPC time constants are matched to the controlled system.

25

In connection with first tests performed during production on the "Chiron FZ 22L" it was possible to increase the kV factor from 1 to 5. However, it was not possible in this case to use the time constant T1 determined from MP26 and MP25. It was necessary to employ a considerably higher time constant (approximately factor 5), which compensates a time constant in the machine.

In addition to "Chiron FZ 22L" a second machine, a Deckel- Mahon "DMU 50 V" was tested.

30

The Deckel-Mahon "DMU 50 V" machine has strong resonances at 42 Hz and 50 Hz. These are so dominant that it is only possible to set a jerk of 10 and an acceleration of 1.5 at kV = 4. By means of the use of the IPC it was possible to achieve a kV of 12 for all axes. The values for jerk could be increased to 20, acceleration was raised to 3.

Time Constants at DMU 50 V:

35

	X-axis	Y-axis	Z-axis
MP25	15	4.8	5.4
MP26	0.045	0.016	0.016

	T1'	0.0042	0.0052	0.0052
	T2'	0.003	0.0022	0.0013
	T1	4.2 ms	5.2 ms	5.2 ms
	T2	3.0 ms	2.2 ms	1.3 ms
5	D	0.70	1.18	2.00

The speed control device settings were not changed (original Deckel-Maho).

Result: A noticeable improvement in the position control device behavior could be achieved with both machines by the use of the IPC.

10

7. IPC Adjustment

When using the IPC it is necessary to differentiate between two types of machines.

15 Type 1 is a rigid machine of not too large structural size, which is mostly directly driven or has linear motors. Type 2 is a machine with a dominant natural frequency in the range between 15 Hz to 80 Hz, in which no sufficiently large kV factor can be set.

7.1 Adjustment of Rigid Machines

20 With machines of the type 1 it is sufficient as a rule if the IPC is switched on with $T1' = 1$ and $T2' = 0$. The kV factor is increased until a noticeable oscillating tendency is noticed in the process.

Once this kV factor has been found, a fine adjustment of the IPC time constant T2 takes place. To this end first a T2 starting value of

25

$$T2 = 2/3 * MP26/MP25$$

is set. Thereafter T2' is changed until a new maximum kV factor has been found. Usually the T2 time constant must be reduced with this machine type (down to maximally 0.5 x the starting value). However, an increase with respect to the starting value is also conceivable.

30

At the end the kV factor for the oscillation threshold must be multiplied by the factor 0.65 in order to assure a sufficient stability of the position control device.

With this type of machine an increase of the kV by a factor of 1.4 to 1.7 is possible.

35

7.2 Adjustment of Machines with Dominant Natural Frequencies

With machines of the type 2, the same adjustment should initially be performed as with machine of the type 1. The IPC must be switched on with $T1' = 1$, and it is necessary to

determine T2. In this case it is also possible that a T2 time constant results which is clearly greater than the T2 starting value.

Now the T1 time constant must be determined. For this purpose a T1 starting value must be entered into MP2602 in place of a 1. It is calculated from

5

$$T1 = MP26/MP25$$

This starting value must be increased until a maximum kV factor has been found. If the found T1 time constant is clearly greater than the starting value (> factor 2), another adjustment of the T2 time component should take place. The value so far found should be lower, or raised, during testing.

10

Finally, the kV factor for the oscillation threshold must be multiplied by the factor 0.65 in order to assure a sufficient stability of the position control device.

15

With machines of the type 2 a greater increase of the kV than by the factor 1.7 is possible.

$$T1_OPT = (J_L * 2 * \pi) / (k_p * K_{MC})$$

wherein J_L : Momentary load,

k_p : Loop gain of the proportional branch of the
speed control device,

K_{MC} : Motor constant.

7. The method in accordance with claim 5, characterized in that subsequently a check is performed whether the previously determined time constant ($T1_OPT$, $T2_OPT$) of the reference model assures the desired control behavior of the control arrangement.

8. The method in accordance with claim 7, characterized in that for this purpose the loop gain (kV) is increased, using the optimized time constant ($T1_OPT$, $T2_OPT$), until an undamped machine oscillation can be registered, and the associated loop gain is used as the second maximum loop gain (kV_{max2}) during the subsequent control operation.

9. The method in accordance with claim 8, characterized in that the determined second maximum loop gain (kV_{max2}) is multiplied by a safety factor K for use in the control operation, wherein $K < 1$.

10. The method in accordance with claim 5, characterized in that thereafter a check is performed whether the selected first time constant ($T1_OPT$) provides an acceptable system behavior, or whether an optimization of the first time constant ($T1$) must be performed.

11. The method in accordance with claim 10, characterized in that in case of a required optimization of the first time constant ($T1$), proceeding from a preset starting value ($T1_{02}$) for the first time constant the first time constant ($T1$) is changed in steps until an undamped machine oscillation can be registered, and the value of the first time constant ($T1$) obtained therefrom is used as the optimized value ($T1_OPT$) for parameterizing the reference model.

12. The method in accordance with claim 11, characterized in that, using the optimized second time constant ($T2_OPT$) and the actual first time constant ($T1$), the loop gain (kV) is increased until an undamped machine oscillation can be registered, and the associated loop gain is used as the second maximum loop gain (kV_{max2}) in the subsequent control operation.

Eingereicht wurde und am March 22, 2002 abgeändert wurde (falls tatsächlich abgeändert).

Ich bestätige hiermit, dass ich den Inhalt der obigen Patentanmeldung einschliesslich der Ansprüche durchgesehen und verstanden habe, die eventuell durch einen Zusatzantrag wie oben erwähnt abgeändert wurde.

Ich erkenne meine Pflicht zur Offenbarung irgendweicher Informationen, die für die Prüfung der vorliegenden Anmeldung in Einklang mit Absatz 37, Bundesgesetzbuch, Paragraph 1.56(a) von Wichtigkeit sind, an.

Ich beanspruche hiermit ausländische Prioritätsvorteile gemäss Abschnitt 35 der Zivilprozessordnung der Vereinigten Staaten, Paragraph 119 aller unten angegebenen Auslandsanmeldungen für ein Patent oder eine Erfindersurkunde, und habe auch alle Auslandsanmeldungen für ein Patent oder eine Erfindersurkunde nachstehend gekennzeichnet, die ein Anmeldedatum haben, das vor dem Anmeldedatum der Anmeldung liegt, für die Priorität beansprucht wird.

As a below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name.

I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled

METHOD FOR DETERMINING TIME CONSTANTS OF A REFERENCE MODEL IN A CASCADE CONTROLLING CIRCUIT

the specification of which

(check one)

☐ is attached hereto.

☒ was filed on March 22, 2002 as

Application Serial No. 10/089,321

and was amended on March 22, 2002 (if applicable)

I hereby state that I have reviewed and understand the contents of the above identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose information which is material to the examination of this application in accordance with Title 37, Code of Federal Regulations, § 1.56(a).

I hereby claim foreign priority benefits under Title 35, United States Code, § 119 of any foreign application(s) for patent or inventor's certificate listed below and have also identified below any foreign application for patent or inventor's certificate having a filing date before that of the application on which priority is claimed:

Ich beanspruche hiermit gemäss Absatz 35 der Zivilprozessordnung der Vereinigten Staaten, Paragraph 120, den Vorzug aller unten aufgeführten Anmeldungen und falls der Gegenstand aus jedem Anspruch dieser Anmeldung nicht in einer früheren amerikanischen Patentanmeldung laut dem ersten Paragraphen des Absatzes 35 der Zivilprozessordnung der Vereinigten Staaten, Paragraph 112 offenbart ist, erkenne ich gemäss Absatz 37, Bundesgesetzbuch, Paragraph 1.56(a) meine Pflicht zur Offenbarung von Informationen an, die zwischen dem Anmeldedatum der früheren Anmeldung und dem nationalen oder PCT internationalen Anmeldedatum dieser Anmeldung bekannt geworden sind.

I hereby claim the benefit under Title 35, United States Code § 120 of any United States application(s) listed below and insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States application in the manner provided by the first paragraph of Title 35, United States Code, § 112, I acknowledge the duty to disclose material information as defined in Title 37, Code of Federal Regulations, § 1.56(a) which occurred between the filing date of the prior application and the national or PCT international filing date of this application:

Ich erkläre hiermit, dass alle von mir in der vorliegenden Erklärung gemachten Angaben nach meinem besten Wissen und Gewissen der vollen Wahrheit entsprechen, und dass ich diese eidesstattliche Erklärung in Kenntnis dessen abgebe, dass wissentlich und vorsätzlich falsche Angaben gemäss Paragraph 1001. Absatz 18 der Zivilprozessordnung der Vereinigten Staaten von Amerika mit Geldstrafe belegt und/oder Gefängnis bestraft werden koennen, und dass derartig wissentlich und vorsätzlich falsche Angaben die Gültigkeit der vorliegenden Patentanmeldung oder eines darauf erteilten Patentes gefährden können.

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application or any patent issued thereon.

German Language Declaration

VERTRETUNGSVOLLMACHT: Als benannter Erfinder beauftrage ich hiermit den nachstehend benannten Patentanwalt (oder die nachstehend benannten Patentanwälte) und/oder Patent-Agenten mit der Verfolgung der vorliegenden Patentanmeldung sowie mit der Abwicklung aller damit verbundenen Geschäfte vor dem Patent- und Warenzeichenamt:
